                                                                                                         f();
```

Function parameters and return values may be of any type. A function must either be declared or defined before it is used. It may be declared first and defined later. Every program consists of a set of a set of global variable declarations and a set of function definitions (possibly in separate files), one of which must be:

```
int main() { statements... } or
int main(int argc, char* argv[]) { statements... }
```

argy is an array of argc strings from the command line. By convention, main returns status 0 if successful, 1 or higher for errors.

Functions with different parameters may have the same name (overloading). Operators except :: . .* ?: may be overloaded. Precedence order is not affected. New operators may not be created.

EXPRESSIONS

Operators are grouped by precedence, highest first. Unary operators and assignment evaluate right to left. All others are left to right. Precedence does not affect order of evaluation, which is undefined. There are no run time checks for arrays out of bounds, invalid pointers, etc.

```
Add 1 to x, evaluates to original x (postfix) Subtract 1 from x, evaluates to original x
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           Convert x to T (obsolete, use .._cast<T>(x))
                                                                                                                                                                        Object of class I initialized with x and y
                                                                                                                                                                                                                                                                                                                                                                                                                                                Add 1 to x, evaluates to new value (prefix)
                                                                                                                                                                                                                                                                                                                                                                                                      Number of bytes used to represent object x

```

Subtract, or number of elements from *x to *y

Add, or &x[y]

+ I

```
struct T {
    virtual void f();    // May be overridden at run time by derived
    class
    virtual void g()=0; }; // Must be overridden (pure virtual)
    class U: public T {};    // Derived class U inherits all members of base
    T
    class V: private T {};    // Inherited members of T become private
    class W: public T, public U {};    // Multiple inheritance
    class X: public virtual T {};    // Classes derived from X have base T
    directly
```

All classes have a default copy constructor, assignment operator, and destructor, which perform the corresponding operations on each data member and each base class as shown above. There is also a default no-argument constructor (required to create arrays) if the class has no constructors. Constructors, assignment, and destructors do not inherit.

TEMPLATES

NAMESPACES

```
namespace N {class T {};} // Hide name T
N::T t;
// Use name T in namespace N
using namespace N; // Make T visible without N::
```

C/C++ STANDARD LIBRARY

Only the most commonly used functions are listed. Header files without .h are in namespace std. File names are actually lower case.

STDIO.H, CSTDIO (Input/output)

```
// Print "x=3" Other conversions:
// int width 5, unsigned int, long left just.
 (0) if error
                                                                                                                                                                                                                                                                    // Print to stdout (screen unless redirected)
                       "rb" binary
                                                                                                                                                                                                                                                                                         // Print to standard error (not redirected)

```
set_new_handler(handler); // Change behavior when out of memory
void handler(void) {throw bad_alloc();} // Default
```

IOSTREAM.H, IOSTREAM (Replaces stdio.h)

```
// Read line into char s[n] to '\n' (default)
// Read words x and y (any type) from stdin
                                                                                                                                                                                                                              istream& operator>>(istream& i, T& x) {i >> ...; x=...; return i;}
                                                                                                                                                                                                                                                            ostream& operator<<(ostream& o, const T& x) {return o << ...;}
                                                                                                                                                                                                  // To read/write any type T:
                                                   // Write to stderr and flush
                                                                                                                                                                           // Good state (not EOF)?
                         // Write line to stdout
                                                                                   // c = getchar();
                                                                                                          // Read char
                         cout << "x=" << 3 << endl;
                                                   cerr << x << y << flush;
                                                                                                                                             '('n'', 'n
                                                                                                                                             cin.getline(s,
  cin >> x >> y;
                                                                                   c = cin.get();
                                                                                                                 cin.get(c);
                                                                                                                                                                         if (cin)
```

FSTREAM.H, FSTREAM (File I/O works like cin, cout as above)

```
ifstream fl("filename"); // Open text file for reading
if (f1)
    // Test if open and input available
    f1 >> x; // Read object from file
    f1.get(s); // Read char or line
    f1.getline(s, n); // Read line into string s[n]
    ofstream f2("filename"); // Open file for writing
if (f2) f2 << x; // Write to file</pre>
```

IOMANIP.H, IOMANIP (Output formatting)

```
cout << setw(6) << setprecision(2) << setfill('0') << 3.1; // print
"003.10"</pre>
```

STRING (Variable sized character array)

```
string s1, s2="hello"; // Create strings
s1.size(), s2.size(); // Number of characters: 0, 5
s1 += s2 + ' + "world"; // Concatenation
s1 == "hello world" // Comparison, also <, >, !=, etc.
s1[0]; // 'h' Substring of size n starting at s1[m]
s1.substr(n, n); // Convert to const char*
getline(cin, s); // Read line ending in '\n'
```

VECTOR (Variable sized array/stack with built in memory allocation)

```
a[0]..a[9] are int (default size is 0)
                                                                                                                                            // Like a[20] but throws out_of_range()
                                                                                                                                                                                                                                                 ರ
                                                                                                                                                                                                                                                 // e is initialized from
                                   // Increase size to 11, a[10]=3
                                                                                                                                                               // Crash: not bounds checked
                                                                                                                                                                                                     vector<int> b(a.begin(), a.end()); // b is copy of a
                // Number of elements (10)
                                                                                                                                                                                                                           // c[0]..c[n-1] init to x
                                                          // a[10]=4;
// Decrease size by 1
                                                                                                  // a[0];
                                                                                                                                                                                                                                                 I d[10]; vector<T> e(d, d+10);
                                                                                                                                                                                                                             vector<T> c(n, x);
vector<int> a(10);
                                      a.push_back(3);
                                                                                a.pop_back();
                                                            a.back()=4;
                                                                                                                                              a.at(20)=1;
                                                                                                      a.front();
                     a.size();
                                                                                                                        a[20]=1;
```

DEQUE (array/stack/queue)

UTILITY (Pair)

```
pair<string, int> a("hello", 3); // A 2-element struct
a.first;
// "hello"
a.second;
// 3
```

MAP (associative array)

ALGORITHM (A collection of 60 algorithms on sequences with iterators)

```
min(x, y); max(x, y); // Smaller/larger of x, y (any type defining <)
swap(x, y); // Exchange values of variables x and y
sort(a, a+n); // Sort array a[0]..a[n-1] by <
sort(a.begin(), a.end()); // Sort vector or deque</pre>
```
